In this section we will deal auguin with the computation of limits. Now we dispose of new tools compared to the beginning of the course, when we used only the definition of limit.

Let us start by reviewing the definition of an "indeterminate

Def: A form of limit is said to be indeterminate when knowing the limit behavior of individual parts of the expression is not sufficient to actually determine the arrall limit.

There exist 7 different indeterminate forms:

Examples

In the beginning of the course we solved this kind of limit by factorizing numerator and denominator:

 $\lim_{x\to 2} \frac{x^2 - 4x + 4}{x^2 - 4} = \lim_{x\to 2} \frac{(x-2)^2}{(x+2)(x-2)} = \lim_{x\to 2} \frac{x-2}{x+2} = 0$

• lim <u>Sin(x)</u> = "0" X+00 x

By a geometric argument it is possible to show

lim <u>sin(x)</u> _ (special limit)

 $\lim_{x\to\infty} \frac{x^2-2}{-x^3-x+1} = \frac{\infty}{\infty}$

This is the limit at infinity of a rational function. We proved that when the degree of the denominator is greater than the degree of the numerator then the result of the limit is o:

 $\lim_{x\to\infty} \frac{x^2-2}{-x^3-x+1} = 0.$

For each one of the praises examples there exist "specific technique" for competing the limit. But what about the following cases? lim ex_1 = "0" line ln(x) = "∞"
X→∞ X-1 = "∞" lim ex = "∞"
x-∞ x² = "∞" Let us consider the first limit: lim ex-1 and let us set: $f(x) = e^{x} - 1$ (Numerator) g(x) = x (denominator) The linearizations of found g man o (x) = {(0) + &'(0) (x-0) = 0 + 1. (x-0) = x 1'(x) = ex $L_g(x) = g(0) + g'(0)(x-0) = 0 + 1 \cdot (x-0) = x$ Then near 0 we have $f(x) \sim L_{g}(x)$ and $g(x) \sim L_{g}(x) \approx that:$ $\lim_{x\to 0} \frac{e^{x}-1}{x} \sim \lim_{x\to 0} \frac{L_{3}(x)}{L_{3}(x)} = \lim_{x\to 0} \frac{x}{x} = \lim_{x\to 0} \frac{1}{x} = 1$ So I is the result that we expect for this limit More in genal, assume that I and g are two furction such that: $\cdot \ f(\alpha) = g(\alpha) = 0$ · the derivative functions of and of one continuous · 9'(x) ≠ 0 near a.

```
We are interested in competing \lim_{x\to a} \frac{d(x)}{d(x)}
If we linearize near a we have:
    f(x) \sim L_g(x) = f(a) + f'(a)(x-a) = f'(a)(x-a);
    g(x) \sim L_{g(x)} = g(a) + g'(a)(x-a) = g'(a)(x-a).
Then
  \lim_{x\to a} \frac{f(x)}{g(x)} \sim \lim_{x\to a} \frac{L_{\varphi}(x)}{L_{\varphi}(x)} = \lim_{x\to a} \frac{f'(a)(x-a)}{g'(a)(x-a)} = \frac{f'(a)}{g'(a)} = \lim_{x\to a} \frac{f'(x)}{g'(x)}
 In conclusion, under particular assumptions we have:
                        \lim_{x\to\infty}\frac{g(x)}{g(x)}=\lim_{x\to\infty}\frac{g'(x)}{g'(x)}
  This result is called "2" Hospital's role" and is stated more formally and in a more general case as follows:
  Theorem (L'HOSPITAL'S RULE)
   Suppose of and gover two differentiable functions and g'(x) 70 near a (except possibly et a).
   Suppose that
        \lim_{x\to a} f(x) = 0 and \lim_{x\to a} g(x) = 0 (\lim_{x\to a} \frac{f(x)}{g(x)} = \frac{a}{2})
      \lim_{x \to a} f(x) = \pm \infty and \lim_{x \to a} g(x) = \pm \infty (\lim_{x \to a} \frac{f(x)}{g(x)} = \frac{f(x)}{g(x)} = \frac{f(x)}{g(x)})
   Then
                       \lim_{x\to a} \frac{d(x)}{d(x)} = \lim_{x\to a} \frac{d'(x)}{d'(x)}
     if the limit on the right side exists (or oo, -oo)
   Remark: L'Hospital's rule applier also in the cases
```

L'Hospital's rule is written sometimes with a different orthography, depending whether we follow the modern or the older French spelling: Wriesity: l'Hospital's rule: OLD L'Hôpital's rule: KODERN Indeed, in the mid 18th century there was a change in French orthography, where some mule 5's were dropped and replaced by the circumflex accent. Examples $\lim_{x\to 2} \frac{x^2 - 4x + 4}{x^2 - 4} = \lim_{x\to 2} \frac{(x^2 - 4x + 4)'}{(x^2 - 4)'} = \lim_{x\to 2} \frac{2x - 4}{2x} = \frac{0}{4} = 0$ 0=>H.R. each time you apply l'Hazeital's role you have to highlight which indeterminate from you are dealing with lim $\frac{\sin(x)}{x}$ = $\frac{\sin(x)}{x}$ = $\frac{\cos(x)}{x}$ = $\cos(x)$ $\lim_{x \to 0} \frac{e^{x} - 1}{x} = \lim_{x \to 0} \frac{(e^{x} - 1)^{1}}{(e^{x})^{1}} = \lim_{x \to 0} \frac{e^{x}}{1} = \frac{e^{0}}{1} = 1$ $\lim_{x\to\infty} \frac{\ln(x)}{\ln(x)} = \lim_{x\to\infty} \frac{1}{|x-x|} = \lim_{x\to\infty} \frac{1}{|x-x|} = 0$ $\lim_{X \to \infty} \frac{e^{x}}{x^{2}} = \lim_{X \to \infty} \frac{(e^{x})'}{(x^{2})'} = \lim_{X \to \infty} \frac{e^{x}}{2x} = \lim_{X \to \infty} \frac{e^{x}}{2} = 60$ $\lim_{X \to \infty} \frac{e^{x}}{x^{2}} = \lim_{X \to \infty} \frac{(e^{x})'}{(x^{2})'} = \lim_{X \to \infty} \frac{e^{x}}{2x} = \lim_{X \to \infty} \frac{e^{x}}{2} = 60$

Remark that l'hospital's rule can be only applied when we are dealing with the indeterminate forms of and on. Neverth less, it is also possible to use l'Hospital's rule with the indeterminate forms 0.00, 00, 100 and 000. Indeed, in each one of these cases it is possible to reduce the indeterminate form to 0 or 00 by doing some "manipulations" on the furtion. Suppose that we want to compute $\lim_{x \to a} f(x) \cdot g(x)$ (*) where $\lim_{x\to a} f(x) = 0$ and $\lim_{x\to a} g(x) = \infty$ We can rewrite (*) in the following ways: · $\lim_{x \to a} f(x) \cdot g(x) = \lim_{x \to a} \frac{f(x)}{f(x)}$ and we can of Hospitalis $\lim_{x \to a} \delta(x) \cdot g(x) = \lim_{x \to a} \frac{g(x)}{\delta(x)}$ Note that both rewriting are correct, but normally one is easier than the other for the compration of the limit. Example lim $\times^2 \ln (x) = \lim_{x \to 0^+} \frac{\ln (x)}{1} = \lim_{x \to 0^+} \frac{(\ln (x))^1}{1} = \lim_{x \to 0^+} \frac{(\ln (x))^$ Note that we could also rewrite in the following way: lin x² ln (x) = lin x² no o

x-oo+ 1

but in this case it is easy to see that l'Hospital's rule
would not simplify the computations.

Suppose that we want to compile lim of(x) of(x) where: lin 1(x)=0 and lin g(x)=0; 2 ling f(x) = 1 and line g(x) = 00; $\lim_{x\to a} f(x) = \infty$ and $\lim_{x\to a} g(x) = 0$. In each one of these cases we rewrite: $\lim_{x\to a} \frac{1}{3} \frac{1}{3} = \lim_{x\to a} e^{\ln \left(\frac{1}{3} \frac{x}{3} \frac{x}{3}\right)} = \lim_{x\to a} e^{2(x) \cdot \ln \left(\frac{1}{3} \frac{x}{3}\right)}$ = ex-00 g(x) en(8(x1)) continuous function Thus the computation of the initial cimit is reduced to the computation of the following on: 0. lu(0) = 0.00 $\lim_{x\to a} g(x) \cdot \ln(f(x))$ $\infty \cdot \ln(1) = \infty \cdot 0$ 0. ln (00) - 0.00 We notice that in all three cases the indeterminate form is reduced to 0.00. Hence, we will use the previous technique for computing the limit. Thus if $\lim_{x\to a} g(x) e_{x}(f(x)) = A \Rightarrow \lim_{x\to a} f(x) = e^{A}$ Examples • lim $x^{\times} = \lim_{x \to 0^{+}} e^{\ln(x^{\times})} = \lim_{x \to 0^{+}} e^{\ln(x)} = \lim_{x \to 0^{+}} e^{\ln(x)}$

Now:

$$\lim_{x \to 0^+} x \otimes h(x) = \lim_{x \to 0^+} \frac{e_h(x)}{1} = \lim_{x \to 0^+} \frac{1}{x} = \lim_{x \to 0^+} \frac{1}{x^2} = \lim_{x \to 0^+} \frac{1}{x^2}$$
